Similarity Models

Edit Distances

Vector/Set similarities and distances

Knowledge-based Approaches

Corpus-based representations

- Similarity models measure how alike are two objects (products, patients, molecules, words, sentences, ...).
- *Similarity* may also be interpreted as *proximity* or *affinity*
- *Similarity* may also be seen as the opposite of *distance*, *difference*, or *divergence*.
- Different uses and applications in AI.

Applications of Similarity Models

Similarity
Models

Edit Distances

Vector/Set
similarities
and distances

Knowledge-
based
Approaches

Corpus-based
representati-
ons

- **Recommendation systems.** E.g. finding similar patients to propose similar treatments, finding similar products to offer them as potentially interesting, find similar news items to recommend, etc.
- **Prediction systems.** (Example-based Learning, EBL). E.g. predict possible diagnoses based on similar patients, predict product sales based on similar products, classify news items based on similar texts, etc.
- **Clustering systems.** E.g.: Group data in clusters to discover new patterns, offer aggregated views to the user, speed up searches, etc.

Applications of Similarity Models to HLT

- **Text similarity tasks:** Plagiarism detection, news items tracking, related readings recommendation, question answering, FAQ management, ...
- **Text analysis tasks:** Tasks such as PoS Tagging, parsing, NERC, etc can be approached using EBL.
- **Text Classification tasks:** (EBL, again). E.g.: news items routing, sentiment analysis, spam detection, ...
- **Evaluation of NL generation tasks:** Evaluate machine translation, automatic summarization, or report generation comparing the system output with reference texts.
- **Alias detection:** (Useful for coreference detection) find different mentions of the same entity (e.g. *Stanford President John Hennessy*, *Stanford University President Hennessy*, *President John Hennessy*, *Stanford Provost John Hindirck*).

Distance, Similarity, & Relatedness

- We talk about *distance* when metric properties hold:
 - $d(x, x) = 0$
 - $d(x, y) > 0$ when $x \neq y$
 - $d(x, y) = d(y, x)$ (simmetry)
 - $d(x, z) \leq d(x, y) + d(y, z)$ (triangular inequation)
- We use *similarity* in the general case
 - Function: $\text{sim} : A \times B \rightarrow S$ (where S is often $[0, 1]$)
 - Homogeneous: $\text{sim} : A \times A \rightarrow S$ (e.g. word-to-word)
 - Heterogeneous: $\text{sim} : A \times B \rightarrow S$ (e.g. word-to-document)
 - Not necessarily symmetric, or holding triangular inequation.
- We can compute one from the other:

$$\text{sim}(A, B) = \frac{1}{1 + d(A, B)}; \quad d(A, B) = \frac{1}{\text{sim}(A, B)} - 1$$

- *Similarity* is often interpreted as a measure of *relatedness*.

Distance, Similarity, & Relatedness

$d(\text{car}, \text{wheel}) > d(\text{car}, \text{truck});$
 $d(\text{car}, \text{dog}) \gg d(\text{car}, \text{truck});$
 $d(\text{cat}, \text{bone}) > d(\text{dog}, \text{bone});$

$\text{sim}(\text{car}, \text{wheel}) < \text{sim}(\text{car}, \text{truck});$
 $\text{sim}(\text{car}, \text{dog}) \ll \text{sim}(\text{car}, \text{truck});$
 $\text{sim}(\text{cat}, \text{bone}) < \text{sim}(\text{dog}, \text{bone});$

Information used to compute similarity

The utility/meaning of a similarity/distance measure depends on how compared objects are represented.

- Information internal to compared units

- Words: char n-grams, word form, lemma, morphology, PoS, sense, domain, ...
- Sentences/Documents: bag of words, parse tree, syntactic roles, collocations, word n-grams, Named Entities, ...

- Information external to compared units (context)

- Words: bag-of-words in context, parse tree, collocations, word n-grams, Named Entities, ...
- Sentences/Documents: Words in nearby sentences, document meta-information, ...

Approaches to Similarity Computation

■ **String/Sequence edit-distance approaches.**

Can only be applied to sequences of elements:

- word : sequence of characters
- sentence : sequence of words (or characters too)
- DNA: sequence of bases A,T,C,G
- Health Record : sequence of clinical events
- ...

■ **Vector/Set based approaches.**

General approach, can be applied to any kind of object once we represent it as a [feature] vector or set.

- Vector similarities/distances
- Set similarities/distances

■ **Knowledge-based approaches.**

- WordNet distances

Some Edit Distances

- LCS (Longest Common Subsequence): ED allowing deletion and insertion.
- Levenshtein: ED allowing deletion, insertion and substitution.
- Damerau-Levenshtein: ED allowing insertion, deletion, substitution, and transposition of two adjacent elements.

Edit distances can be efficiently computed using dynamic programming.

Example: Levenhstein

```
1 def Levenshtein(s, t):
2
3     n = len(s)
4     m = len(t)
5     d = [ [ 0 for j in range(0,m+1) ] for i in range(0,n+1) ]
6
7     # source prefixes can be transformed into empty string by
8     # dropping all characters
9     for i in range(1,n+1): d[i][0] = i
10
11    # target prefixes can be reached from empty source prefix
12    # by inserting every character
13    for j in range(1,m+1): d[0][j] = j
14
15    for i in range(1,n+1):
16        for j in range(1,m+1):
17
18            subst = 0 if s[i-1] == t[j-1] else 1 # substitution cost
19
20            d[i][j] = min(d[i-1][j] + 1, # deletion
21                        d[i][j-1] + 1, # insertion
22                        d[i-1][j-1] + subst) # substitution
23
24    return d[n][m]
```

Vector similarities/distances

When objects are represented as [feature] vectors, we can use vector-space distances.

- Manhattan distance
- Euclidean distance
- Chebychev distance
- Canberra distance
- Cosine *similarity*
- Dot Product *similarity*
- ...

Vector similarities/distances

Similarity
Models

Edit Distances

Vector/Set
similarities
and distances

Vector similarities
and distances

Knowledge-
based
Approaches

Corpus-based
representati-
ons

- Commonly used norms belong to the family of Minkowsky distances:

$$d_{\min}(\vec{x}, \vec{y}) = L_r(\vec{x}, \vec{y}) = \left(\sum_{i=1}^N |x_i - y_i|^r \right)^{\frac{1}{r}}$$

- L_1 and L_2 norms are particular cases of orders 1 and 2
- Chebychev distance is the limit L_∞ .

Vector similarities/distances

- L_1 norm, a.k.a. Manhattan distance, taxi-cab distance, city-block distance:

$$d_{\text{man}}(\vec{x}, \vec{y}) = L_1(\vec{x}, \vec{y}) = \sum_{i=1}^N |x_i - y_i|$$

Vector similarities/distances

- L_2 norm, a.k.a. Euclidean distance:

$$d_{\text{euc}}(\vec{x}, \vec{y}) = L_2(\vec{x}, \vec{y}) = |\vec{x} - \vec{y}| = \sqrt{\sum_{i=1}^N (x_i - y_i)^2}$$

Vector similarities/distances

- The limit of Minkowsky distance is Chebychev distance:

$$d_{che}(\vec{x}, \vec{y}) = L_{\infty} = \lim_{r \rightarrow \infty} L_r(\vec{x}, \vec{y}) = \max_i |x_i - y_i|$$

Vector similarities/distances

- Cosine is a similarity, not a distance:

$$\text{sim}_{\cos}(\vec{x}, \vec{y}) = \cos(\vec{x}, \vec{y}) = \frac{\vec{x} \cdot \vec{y}}{|\vec{x}| \cdot |\vec{y}|} = \frac{\sum_i x_i y_i}{\sqrt{\sum_i x_i^2} \cdot \sqrt{\sum_i y_i^2}}$$

Vector/Set
similarities
and distances

Vector similarities
and distances

Knowledge-
based
Approaches

Corpus-based
representati-
ons

Vector similarities/distances

- Dot product (or scalar product) is also similarity, that takes into account not only the angle but also the norm of the vectors:

$$\text{sim}_{\text{dot}}(\vec{x}, \vec{y}) = \vec{x} \cdot \vec{y} = \sum_i x_i y_i$$

$$\begin{aligned}\text{sim}_{\cos}(X, Z) &= \text{sim}_{\cos}(Y, Z) \\ &= \cos \alpha \approx 0.84\end{aligned}$$

$$\text{sim}_{\text{dot}}(X, Z) = |X| \cdot |Z| \approx 8.2$$

$$\text{sim}_{\text{dot}}(Y, Z) = |Y| \cdot |Z| \approx 21.3$$

Vector similarities/distances

- Camberra distance is similar to L_1 but relative to the distance to origin:

$$d_{\text{cam}}(\vec{x}, \vec{y}) = \sum_{i=1}^N \frac{|x_i - y_i|}{|x_i + y_i|}$$

Set similarities and
distances

Knowledge-
based
Approaches

Corpus-based
representati-
ons

Set similarities/distances

- When objects are represented as [feature] sets (or binary-valued vectors) we can use set similarity measures
- These similarities are in $[0, 1]$ and can be converted to distances simply subtracting: $d(X, Y) = 1 - \text{sim}(X, Y)$
- Easily computable using a contingency table:

		Y		
		1	0	
X	1	a	b	a + b
	0	c	d	c + d
		a + c	b + d	

Set similarities/distances

■ Dice.

$$\text{sim}_{\text{dic}}(X, Y) = \frac{2 \cdot |X \cap Y|}{|X| + |Y|} = \frac{2a}{2a + b + c}$$

■ Jaccard.

$$\text{sim}_{\text{jac}}(X, Y) = \frac{|X \cap Y|}{|X \cup Y|} = \frac{a}{a + b + c}$$

Set similarities/distances

■ Overlap.

$$\text{sim}_{\text{ovl}}(X, Y) = \frac{|X \cap Y|}{\min(|X|, |Y|)} = \frac{a}{\min(a + b, a + c)}$$

■ Cosine.

$$\text{sim}_{\text{cos}}(X, Y) = \frac{|X \cap Y|}{\sqrt{|X|} \cdot \sqrt{|Y|}} = \frac{a}{\sqrt{(a + b)} \sqrt{(a + c)}}$$

Set similarities/distances

■ Matching Coefficient

$$\text{sim}_{\text{mc}}(X, Y) = \frac{|X \cap Y| + |(\Omega - X) \cap (\Omega - Y)|}{|\Omega|} = \frac{a + d}{a + b + c + d}$$

Knowledge-based Approaches

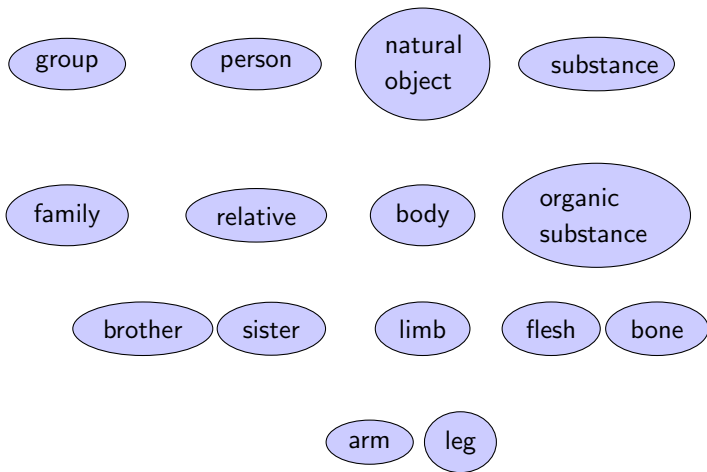

Project objects onto a knowledge-based semantic space:

$$d(x, y) = d_{\text{sem}}(f(x), f(y))$$

- Semantic spaces may be ontologies (e.g. WordNet, CYC, SUMO, ...) or graph-shaped knowledge bases (e.g. Wikipedia, DBpedia, ...).
- Projection function $f(x)$ is not trivial, since each word may map to more than one concept in semantic space.

WordNet distances

Based on graph structure:

- Shortest Path Length:

$$d(s_1, s_2) = \text{SLP}(s_1, s_2)$$

- Leacock & Chodorow (similarity, $[0, \infty)$):

$$s(s_1, s_2) = -\log \frac{\text{SLP}(s_1, s_2)}{2 \cdot \text{MaxDepth}}$$

- Wu & Palmer (similarity, $(0, 1]$):

$$d(s_1, s_2) = \frac{2 \cdot \text{depth}(\text{LCS}(s_1, s_2))}{\text{depth}(s_1) + \text{depth}(s_2)}$$

WordNet distances

Based on Information Content

$$IC(c) = -\log P(c) = -\log \frac{\text{freq}(c)}{N}$$

$\text{freq}(c)$: number of occurrences of *any instance* of concept c .

N : total number of observed instances.

- Resnik (similarity, $[0, \infty)$)

$$s(s_1, s_2) = IC(LCS(s_1, s_2))$$

- Jiang & Conrath (distance, $[0, \infty)$)

$$d(s_1, s_2) = IC(s_1) + IC(s_2) - 2 \cdot IC(LCS(s_1, s_2))$$

- Lin (similarity, $[0, 1]$):

$$s(s_1, s_2) = \frac{2 \cdot IC(LCS(s_1, s_2))}{IC(s_1) + IC(s_2)}$$

Vectors to represent linguistic objects may be build using the distributional behaviour of the contexts they appear in.

E.g.:

- Represent words depending on the distribution of words frequently appearing nearby.
- Represent documents depending on the [general] distribution of words they contain.

Large corpus are required to pre-compute this distributions.

Corpus based representations

Vectors representing words or document contexts can be obtained in a variety of ways.

- Sparse vector representations
 - PMI
 - TF-IDF
- Dense vector representations
 - LSI
 - LDA
 - Word Embeddings

Term-Term Matrix
(using PMI)

PMI - Pointwise Mutual Information

- Mutual Information of two random variables X , Y measures the amount of information about one random variable obtained observing the other.

$$MI(X, Y) = \sum_{x \in X} \sum_{y \in Y} P(x, y) \log \frac{P(x, y)}{P(x)P(y)}$$

- Pointwise MI measures the ratio between the expected co-occurrence of events x and y , and their actual co-occurrence.

$$PMI(x, y) = \log \frac{P(x, y)}{P(x)P(y)}$$

Term-Term Matrix

PMI (or any other term-term relatedness feature, e.g. co-occurrence frequency) may be used to build a Term-Term Matrix.

Co-occurrence is typically defined as *co-occurrence in a window of size n* . In this example $n = 2$ (i.e. we count only consecutive words co-occurrences).

d_1 : "Two for tea and tea for two"

d_2 : "Tea for me and for you"

d_3 : "You and me for tea"

	two	for	tea	and	me	you	#occ.
two	0	2	0	0	0	0	2
for	-	0	4	1	2	1	5
tea	-	-	0	2	0	0	4
and	-	-	-	0	2	1	3
me	-	-	-	-	0	0	2
you	-	-	-	-	-	0	2

size-2 window co-occurrence absolute frequency term-term matrix

Term-Term Matrix

We need to compute the occurrence probability of a single word $P(x)$, and the co-occurrence probability of two words $P(x, y)$.

d_1 : "Two for tea and tea for two"

d_2 : "Tea for me and for you"

d_3 : "You and me for tea"

Total words: 18

Total size-2 windows: 15

$P(x, y)$	two	for	tea	and	me	you	$P(x)$
two	0	2/15	0	0	0	0	2/18
for	-	0	4/15	1/15	2/15	1/15	5/18
tea	-	-	0	2/15	0	0	4/18
and	-	-	-	0	2/15	1/15	3/18
me	-	-	-	-	0	0	2/18
you	-	-	-	-	-	0	2/18

size-2 window co-occurrence probability term-term matrix

Term-Term Matrix

We can compute PMI for each pair, obtaining a PMI Term-Term Matrix

d_1 : "Two for tea and tea for two"

d_2 : "Tea for me and for you"

d_3 : "You and me for tea"

Total words: 18

Total bigrams: 15

PMI(x, y)	two	for	tea	and	me	you	P(x)
two	$-\infty$	2.11	$-\infty$	$-\infty$	$-\infty$	$-\infty$	0.11
for	-	$-\infty$	2.11	0.53	2.11	1.11	0.28
tea	-	-	$-\infty$	1.85	$-\infty$	$-\infty$	0.22
and	-	-	-	$-\infty$	2.85	0.56	0.17
me	-	-	-	-	$-\infty$	$-\infty$	0.11
you	-	-	-	-	-	$-\infty$	0.11

PMI term-term matrix

Term-Term Matrix

- Entries in the Term-Term Matrix can directly be used to compare two terms (higher PMI - higher relatedness)
- Rows (or columns) in the Matrix can be used as term representations, and compared with vector similarity measures (to find terms with similar co-occurrence patterns).
- Negative PMI represent terms that *repel* each other (co-occur less than expected).
- Very low frequency terms may have negative PMI just because they have less chances to co-occur.
- Negative PMI values are often replaced by zero (PPMI - Positive PMI)

Term-Document
Matrix (using
TF-IDF)

TF-IDF

TF-IDF (*Term Frequency* \times *Inverse Document Frequency*) is a measure of relevance (or relatedness) between a term and a document, very commonly used in Information Retrieval.

$$\text{TF-IDF}(t, d, \mathcal{D}) = \text{TF}(t, d) \times \text{IDF}(t, \mathcal{D})$$

where:

- \mathcal{D} is a collection (set) of documents,
 $\mathcal{D} = \{d_1, d_2, \dots, d_n\}$
- $d_i \in \mathcal{D}$ is a document, represented as a multiset (i.e. set with repetitions) of terms,
 $d_i = \{t_1, t_2, \dots, t_{m_i}\}$
- t is a term that may appear (or not) in documents in \mathcal{D} .

TF-IDF

- $TF(t, d)$: Frequency of a term t in a document d , relative to the length of the document

$$TF(t, d) = \frac{|\{x \in d : x = t\}|}{|d|}$$

- $IDF(t, \mathcal{D})$: Inverse of the proportion of documents containing term t in a document collection \mathcal{D} .

$$IDF(t, \mathcal{D}) = \log \left(\frac{|\mathcal{D}|}{|\{d \in \mathcal{D} : t \in d\}|} \right)$$

TF-IDF score for a term t and a document d is rewarded when the term is frequent in the document (high TF), and is penalized when the term appears in many documents (low IDF).

Term-Document Matrix

TF-IDF (or any other term-document relatedness measure, e.g. plain frequency) can be used to build a Term-Document Matrix:

d_1 : "Two for tea and tea for two"

d_2 : "Tea for me and for you"

d_3 : "You and me for tea"

	two	for	tea	and	me	you	$ d_i $
d_1	2	2	2	1	0	0	7
d_2	0	2	1	1	1	1	6

d_3	0	0	0	0	0.117	0.117	5

TF-IDF term-document matrix

Term-Document Matrix

TF-IDF table entries contain the *relevance* (or *relatedness*, or *similarity*, ...) between terms and documents, and can be used for IR.

- A query with the term *two* will retrieve document *d₁* with high relevance.
- A query with the term *me* or *you* will retrieve documents *d₂* and *d₃* with moderate relevance.
- Terms *for*, *and*, or *tea* would be filtered out from the index.

	two	for	tea	and	me	you	d _i
d ₁	0.45	0	0	0	0	0	7
d ₂	0	0	0	0	0.097	0.097	6
d ₃	0	0	0	0	0.117	0.117	5

TF-IDF term-document matrix

Term-Document Matrix

The Term-Document matrix may also be used as a representation of terms/documents:

- Row vectors in the matrix represent documents.

We can use vector distances/similarities to compare row vectors and find similar documents.

- Column vectors in the matrix represent terms.

We can use vector distances/similarities to compare column vectors and find similar terms.

Term-Document Matrix

In the running example:

- Documents d_2 and d_3 are similar documents, quite different from d_1 .
- Terms *me* and *you* behave similarly (wrt the documents where they appear).
- Terms *and*, *for*, and *tea* behave similarly (wrt the documents where they appear).

	two	for	tea	and	me	you	$ d_i $

Dense
representations

Sparse vs. Dense Representations

Term-Term and Term-Document Matrices are typically sparse:

- A term co-occurs with only a small subset of all possible terms.
- A document contains only a small subset of all possible terms.

Dense representations are preferred:

- Lower dimensionality spaces, less features to deal with.
- Better generalization:
E.g., better handling of synonyms (*car* and *automobile* are different dimensions in a sparse representation, but may be combined into one dimension in a dense representation.)

Dimensionality Reduction

Similarity
Models

Edit Distances

Vector/Set
similarities
and distances

Knowledge-
based
Approaches

Corpus-based
representati-
ons

Dense
representations

To obtain dense representations, a dimensionality reduction must be performed.

Distributional semantics methods are appropriate:

- Latent Semantic Analysis (LSA, a.k.a. Latent Semantic Indexing, LSI)
- Word Embeddings

Latent Semantic Analysis

Goal: Reduce dimensionality of Term-Document matrix M .

Method: Apply SVD (Singular Value Decomposition):

$$M = U\Sigma V^T$$

basically, apply PCA (Principal Component Analysis) to Term-Document co-occurrence matrices.

Σ is a diagonal matrix containing the **singular values**, and U, V are **orthonormal matrices** ($UU^T = U^TU = I$; $VV^T = V^TV = I$)

Latent Semantic Analysis (2)

Reduce M rank selecting the k largest singular values, obtaining M_k , a low-rank approximation of M :

$$M \approx M_k = U_k \Sigma_k V_k^T$$

Similarity
Models

Edit Distances

Vector/Set
similarities
and distances

Knowledge-
based
Approaches

Corpus-based
representati-
ons

LSA

Latent Semantic Analysis (3)

We can then compute low rank representations for document and term vectors:

- low-rank term vector: $\hat{t}_i = \Sigma_k^{-1} V_k^T t_i$ (see proof 1)
- low-rank document vector: $\hat{d}_j = \Sigma_k^{-1} U_k^T d_j$ (see proof 2)

And use them to compute similarities:

- Term-term similarity: Entry ij in $M_k M_k^T$, i.e. dot product of $\Sigma_k \hat{t}_i$ and $\Sigma_k \hat{t}_j$ (see proof 3)
- Doc-doc similarity: Entry ij in $M_k^T M_k$, i.e. dot product of $\Sigma_k \hat{d}_i$ and $\Sigma_k \hat{d}_j$ (see proof 4)
- Query-doc similarity: Convert query (seen as a mini-document vector) to low-rank space $\hat{q} = \Sigma_k^{-1} U_k^T q$ and compare with known documents.

Latent Semantic Analysis (proofs)

■ Proof 1:

$$\mathbf{t}_i^T = \hat{\mathbf{t}}_i^T \Sigma_k \mathbf{V}_k^T \rightarrow \mathbf{t}_i^T \mathbf{V}_k = \hat{\mathbf{t}}_i^T \Sigma_k \rightarrow \mathbf{t}_i^T \mathbf{V}_k \Sigma_k^{-1} = \hat{\mathbf{t}}_i^T \rightarrow \hat{\mathbf{t}}_i = \Sigma_k^{-1} \mathbf{V}_k^T \mathbf{t}_i$$

■ Proof 2:

$$\mathbf{d}_j = \mathbf{U}_k \Sigma_k \hat{\mathbf{d}}_j \rightarrow \mathbf{U}_k^T \mathbf{d}_j = \Sigma_k \hat{\mathbf{d}}_j \rightarrow \Sigma_k^{-1} \mathbf{U}_k^T \mathbf{d}_j = \hat{\mathbf{d}}_j$$

■ Proof 3:

$$\begin{aligned} \mathbf{M}_k \mathbf{M}_k^T &= \mathbf{U}_k \Sigma_k \mathbf{V}_k^T (\mathbf{U}_k \Sigma_k \mathbf{V}_k^T)^T = \mathbf{U}_k \Sigma_k \mathbf{V}_k^T (\mathbf{V}_k \Sigma_k^T \mathbf{U}_k^T) = \\ &= \mathbf{U}_k \Sigma_k \mathbf{I} \Sigma_k^T \mathbf{U}_k^T = \mathbf{U}_k \Sigma_k (\mathbf{U}_k \Sigma_k)^T \end{aligned}$$

Thus, element ij in the matrix is:

$$\mathbf{t}_i^T \Sigma_k (\mathbf{t}_j^T \Sigma_k)^T = \mathbf{t}_i^T \Sigma_k \Sigma_k^T \mathbf{t}_j = \Sigma_k^T \mathbf{t}_i \Sigma_k^T \mathbf{t}_j = \Sigma_k \mathbf{t}_i \Sigma_k \mathbf{t}_j$$

■ Proof 4:

$$\begin{aligned} \mathbf{M}_k^T \mathbf{M}_k &= (\mathbf{U}_k \Sigma_k \mathbf{V}_k^T)^T \mathbf{U}_k \Sigma_k \mathbf{V}_k^T = (\mathbf{V}_k \Sigma_k^T \mathbf{U}_k^T) \mathbf{U}_k \Sigma_k \mathbf{V}_k^T = \\ &= \mathbf{V}_k \Sigma_k^T \mathbf{I} \Sigma_k \mathbf{V}_k^T = \mathbf{V}_k \Sigma_k \Sigma_k^T \mathbf{V}_k^T = \mathbf{V}_k \Sigma_k (\mathbf{V}_k \Sigma_k)^T \end{aligned}$$

Thus, element ij in the matrix is:

$$\mathbf{d}_i^T \Sigma_k (\mathbf{d}_j^T \Sigma_k)^T = \mathbf{d}_i^T \Sigma_k \Sigma_k^T \mathbf{d}_j = \Sigma_k^T \mathbf{d}_i \Sigma_k^T \mathbf{d}_j = \Sigma_k \mathbf{d}_i \Sigma_k \mathbf{d}_j$$

LSA

Word Embeddings

Goal: Find a low-rank representation for terms.

Method: Train a neural network to learn appropriate low-rank vectors for each term.

- Word w_i appearing near context words c_1, c_2, c_3 is used as a training example.
- The NN learns to relate words to their usual context words.
- The hidden layer input weights encode the usual contexts of each input word.
- Words usually appearing in similar context will have similar hidden layer weights.

Word Embeddings

■ LSA

- Allows comparing not only words, but also documents
- Requires managing documents
- Traditionally used in IR

■ WE

- Allows comparing only words, but not documents
- No need to manage/represent documents
- Learned vectors show analogy properties (man \rightarrow king, woman \rightarrow X?)
- Natural approach when using NN
